

1. For $n = 100$, what fraction of the 10,000 $\bar{X}$ bars were in the range?
0.0778
2. How does the fraction depend on n ?⁺
It increases with n
3. For $n=100$, what is the range $[-\epsilon, \epsilon]$ for which 99% of the 10,000 $\bar{X}$ bars fall in?
0.26
4. How does epsilon depend on n (for the 99% case of part 3.)?⁺
It is inversely proportional to n
5. How does your answer change if the distribution changes (that is, if you draw values from a distribution other than Gaussian)?
They should be the same
